

IN THE CLAIMS:

Please amend claims 1, 9, 10, and 11 in "clean" format, as follows:

1. (Amended) An electroluminescence device, comprising:

an electroluminescence element having a light emissive layer provided between first and second electrodes;

a first thin film transistor receiving a selection signal at its gate to acquire a data signal; and

a second thin film transistor provided between a driving power supply and said electroluminescence element, and controlling power supplied from said driving power supply to said electroluminescence element in accordance with the data signal supplied from said first thin film transistor; wherein

said first thin film transistor is a double gate type having a lightly doped drain structure, said first thin film transistor has an n-channel, an offset structure, and a multigate structure; and

said second thin film transistor has a p-channel.

9. (Amended) An electroluminescence display device, comprising:

an electroluminescence element having a light emissive layer provided between an anode and a cathode;

a first thin film transistor having an active layer which is formed of a non-single crystalline semiconductor film and which includes a source connected to a storage capacitor, a drain connected to a drain signal line, and a gate electrode provided over a channel of said active layer and connected to a gate signal line; and

a second thin film transistor having an active layer which is formed of a non-single crystalline semiconductor film and which includes a drain connected to a driving power supply of said electroluminescence element, and a gate electrode connected to the source of said first thin film transistor; wherein

said first thin film transistor is a double gate type having a lightly doped drain structure, said first thin film transistor has an n-channel, an offset structure, and a multigate structure; and

said second thin film transistor has a p-channel.

Sub B2
10. (Amended) An electroluminescence display device, comprising:
an electroluminescence element having a light emissive layer provided between an anode and a cathode;

a first thin film transistor having an active layer which is formed of a non-single crystalline semiconductor film and which includes a source connected to a storage capacitor, a drain connected to a drain signal line, and a gate electrode provided under a channel of said active layer and connected to a gate signal line; and

a second thin film transistor having an active layer which is formed of a non-single crystalline semiconductor film and which includes a drain connected to a driving power supply of said electroluminescence element, and a gate electrode connected to the source of said first thin film transistor; wherein

Cont'd
H2
said first thin film transistor is a double gate type having a lightly doped drain structure, said first thin film transistor has an n-channel, an offset structure, and a multigate structure; and

said second thin film transistor has a p-channel.

11. (Amended) A light emissive device, comprising:

a light emissive element having a light emissive layer provided between first and second electrodes;

a first thin film transistor receiving a selection signal at its gate to acquire a data signal; and

a second thin film transistor provided between a driving power supply and said element, and controlling power supplied from said driving power supply to said element in accordance with the data signal supplied from said first thin film transistor; wherein

said first thin film transistor is a double gate type having a lightly doped drain structure, said first thin film transistor has an n-channel, an offset structure, and a multigate structure; and

said second thin film transistor has a p-channel.
